FAQ's

1) What is run-time polymorphism?

→ It is the ability to resolve function calls dynamically at execution time based on the actual object type than the pointer type.

2) What is a virtual function?

→ A member function declared in a base class using the virtual keyword that can be overriden & dynamically dispatched in derived classes.

3) What is dynamic binding?

→ The mechanism where the function code to be executed is linked or chosen at run time rather than compile time.

4) What is a pure virtual function?

→ A virtual function declared with =0 that has no implementation in the base class & makes the class abstract.

5) Why should a polymorphic base class generally have a virtual destructor?

→ To ensure that destructor code for derived classes executes properly when objects are deleted through base class pointers.
